

Refrigerant Troubleshooting

Pressure switch issue

If your condenser is cycling on then off fast most likely the pressure switch is causing this. The best thing to do is turn your system off. The pressure switch is causing this because your freon pressures are not correct. They are either too high or too low. This doesn't always means your system is low on freon or has too much. There are other things that can cause the pressures to be incorrect. The pressure switch or control board could also be faulty as well. This is less likely, most of the time a pressure switch or board is bad the system will not run at all. A service technician should be called to troubleshoot your system.
